Fundy Model Forest Project Report

Deer Winter Habitat Projections

The purpose of this project was to project the occurrence of stands that meet the winter habitat requirements of deer in the SNB area as a result of SNB's current SFM plan. This information would then be added to the existing SNB SFM system and also provided to the Fundy Model Forest so that the information can be added to their system as well.

SNB approached Group 5 (Multiple Benefits to Society) of the Fundy Model Forest to help fund the projection of potential deer winter habitat. The group was interested in the project because it filled an information gap and addressed indicator 5.1e with regards to the private forestland in the SNB / FMF areas. The on the ground benefits of this project will be primarily seen in the influence it will have on the development of woodlot management plans. The hope is that this landscape level concern will be increasingly incorporated into woodlot level management plans.

To project the potential deer winter habitat (DWH) over the planning horizon of the SNB SFM plan there were several steps that had to be completed along the way. These steps included:

1. Apply DWH habitat definitions to the appropriate forest stands

Using the deer winter habitat definitions from the NB DNRE the stand level yield curves that had the proper attributes such as species composition and volume were selected and the habitat windows were applied. These habitat windows define when, in terms of the age, the stand will provide deer wintering habitat (Table 1.).

2. Adding DWH yield component to appropriate stand yield curves.

Once the eligible yield curves were selected and the habitat windows determined, a new yield component was added to these yield curves. These new yield components were then added to SNB's existing wood supply analysis model.

3. Modifying SNB's current wood supply model to report on DWH

SNB's current wood supply analysis model was modified to report on the area of deer winter habitat for each five-year period between 1994 and 2074.

4. Re-running of SNB's preferred scenario.

The modified SNB wood supply model was then re-run using SNB's preferred scenario to gauge the impacts of this management strategy on the availability of deer winter habitat over the current planning period.

From a previous deer winter habitat project it has been calculated that for the year 1994 there was 49168 ha of moderate winter DWH and 31148 ha of severe winter habitat in the SNB/FMF areas. The task of this project was to project these habitat levels over time as a result of SNB's current SFM plan. The projected areas of deer winter habitat for the SNB area for the time period 1994 – 2074 are shown in the table and graph below. (Table 2. and Fig. 1)

Table 2.

Area of deer winter habitat by type of habitat provided (SNB Area)			
Planning Period	Moderate Winter DWH	Severe Winter DWH	Total Area (ha)
P0	49168	31148	80316
P1	39533	30271	69804
P2	40935	23760	64695

Fig. 1.

As an addition to this project group 5 upon approval of the deer winter habitat projection project asked SNB to also include the NBDNRE mature coniferous forest habitat (MCFH) and mature deciduous forest habitat (MDFH) in the re-run of SNB's wood supply analysis model. Adding the MCFH and MDFH windows to the model was done in the same manor as the DWH windows, and so the steps will not be repeated here. The projected areas of MCFH and MDFH for the SNB area for the time period 1994 – 2074 are shown in the table and graph below. (Table 3., Fig. 2 and Fig. 3)

Table 3.

Area of Mature Forest Habitat (SNB Area)			
Planning Period	Area MCFH	Area MDFH	Total Area (ha)
P0	73149	46566	119715
